The concept of transmission line transformers (TLTs, also known as equal delay transformers) has been a distinct element of RF circuit design since at least 1944, when Guanella disclosed an impedance transformer of novel design which consisted of a pair of interconnected transmission lines [1, 2]. TLTs have been found to possess far wider bandwidth and much greater transmission efficiencies by arranging the windings of the TLT to have uniform transmission line properties.

This has made it challenging for many magnetic manufacturers to supply compact high-power high frequency transformers. ATL offer a family of high frequency transformers, low power transformers, high power high frequency transformers, high voltage high frequency transformers and Planar transformers for modern applications.

In radio-frequency engineering, a transmission line is a specialized cable or other structure designed to conduct alternating current of radio frequency, that is, currents with a frequency high enough that their wave nature must be taken into account. Transmission lines are used for purposes such as connecting radio transmitters and receivers with their antennas, distributing cable television signals, trunklines routing calls between telephone switching centres, computer network connections and

A line trap, also known as wave trap, or high-frequency stopper, is a maintenance-free parallel resonant circuit, mounted inline on high-voltage AC transmission power lines to prevent the transmission of high frequency carrier signals of power line communication to unwanted destinations. Line traps are cylinder-like structures connected in series with HV transmission lines. A line trap is also called a wave trap. The line trap acts as a barrier or filter to prevent signal losses. The inductive r
